## ABSTRACT

4

5 Disclosed is a device for holding and supporting an  
6 infant, which consists of a base including a proximal  
7 extremity, an opposing distal extremity, and an edge  
8 therebetween. The base has an inclined surface extends  
9 from the proximal extremity to the edge, and a generally  
10 horizontal surface extends from the edge to the distal  
11 extremity. A body-supporting harness assembly, located  
12 atop the inclined surface, is attached to the base and is  
13 movable between a first body supporting position away from  
14 the general horizontal surface and a second position toward  
15 the generally horizontal surface.
